 Sensitivity analysis

ABSTRACT

Viability of Artificial Neural Network (ANN) in predicting unconfined compressive strength (UCS) of geopolymer stabilized clayey soil has been investigated in this paper. Factors affecting UCS of geopolymer stabilized clayey soil have also been reported. Ground granulated blast furnace slag (GGBS), fly ash (FA) and blend of GGBS and FA (GGBS + FA) were chosen as source materials for geo-polymerization. 28 day UCS of 283 stabilized samples were generated with different combinations of the experimental variables. Based on experimental results ANN based UCS predictive model was devised. The prediction performance of ANN model was compared to that of multi-variable regression (MVR) analysis. Sensitivity analysis employing different methods to quantify the importance of different input parameters were discussed. Finally neural interpretation diagram (NID) to visualize the effect of input parameters on UCS is also presented.

1. Introduction

Geopolymer technology is a recent field of research interest in concrete science and engineering and is gaining increasing attention for utilization of industrial by products such as FA and GGBS. Any pozzolanic material containing source of silica and alumina that is readily dissolved in the alkaline solution acts as a source of geopolymer precursor species and lends itself to geopolymerization [1]. Geopolymerization involves the poly-condensation reaction of polysilicic precursors i.e. alumino-silicate oxide with alkali polysilicates yielding polymeric Si–O–Al bond as shown below [2–4].

where M is the alkaline element, z is 1, 2 or 3 and n is the degree of poly-condensation [4]. It is worthwhile to mention that the micro-structure of the end product formed after geopolymerization is totally different from that of pozzolanic reactions since pozzolanic reaction yields calcium silicate hydrate and/or calcium alumino-silicate [5].

Review of literature reveals that limited research have been carried out on soil stabilization by geopolymer binder. In recent past,

FA based geopolymer was successfully used by some researchers for improvement of clayey soil [6–9]. However, in most of the cases, the specimens were cured either at elevated temperature or at ambient temperature for a prolonged period, sometimes up to one year. Zhang et al. [10] studied the feasibility of metakaolin based geopolymer as a next generation soil stabilizer. GGBS-based geopolymer binder shows very high strength within hours and yet doesnot require elevated temperature curing [11,12]. Till date, rare literatures are reported on the effectiveness of GGBS-based geopolymer soil stabilization. Only recently, Yaolin et al. [13] investigated the effect of several alkali activators on the stabilization efficacy of GGBS treated marine soft clay. Detail investigation on role of parameters such as binder content, alkali to binder ratio and molar strength of alkali affecting mechanical properties of GGBS based geopolymer stabilized soil is yet to be explored.

In the present study, an effort has been made to stabilize clayey soil by GGBS based geopolymer. Source materials such as FA and blend of GGBS + FA were also incorporated in the present study to compare the stabilization efficacy among them and were reported via 28 day UCS. For optimal and effective stabilization, ANN based UCS predictive model was developed. Prediction efficacy of developed ANN model was compared with that of MVR model. Sensitivity analysis was employed to understand the effect and to quantify the importance of different input geopolymer mix parameters on the predicted UCS of stabilized specimens.

2. Experimental procedure

2.1. Material used

Three different types of soil designated as S₁, S₂ and S₃ in the present study were undertaken. The soils were collected from three different locations in Silchar city within 2 m of the ground surface. The engineering properties of the soils conforming to relevant Indian Standard Code of Practice are presented in Table 1. Commercially available ultra-fine GGBS and ASTM class F fly ash collected from thermal power plant at Farakka (India) was used as source material. The chemical and physical characteristics of GGBS and FA are presented in Table 2. Sodium hydroxide was chosen in the present study as alkali activator because of its greater capacity to liberate silicate and aluminate monomers [14]. Commercial grade sodium hydroxide (NaOH) pallets with purity 98%, specific gravity 2.13 and molecular weight 40 were used in the present study. Sodium silicate is often used along with sodium hydroxide for alkali activation as the presence of sodium silicate in sodium hydroxide is believed to enhance the reaction kinetics of geopolymerization [15]. In the present study, sodium silicate (Na₂SiO₃) combined with sodium hydroxide was used only in few cases to produce variations in some of the experimental variables, details of which will be dealt in subsequent sections. Sodium silicate used in the study had a specific gravity of 1.5, 97% purity and a molecular weight (Na₂SiO₃·5H₂O) equal to 212. The alkali solution was prepared with tap water one day prior to use.

2.2. Methodology

The requisite quantity of clay soil weighed to the nearest gram was oven dried for 24 h at 110 ± 5 °C and then thoroughly mixed with source materials in a kitchen appliance until a uniform mix was obtained. Amount of binder were varied as a percentage of dry weight of soil solids from 4–50% for GGBS, 4–20% for FA and blend GGBS + FA. Molar concentration of alkali solution (M) used in the present study were 4 M, 8 M, 10 M, 12 M and 14.5 M. Alkali solution was added to the mix and the mixing was continued for 15 min. In literature, a mixing time of 10–20 min is reported for obtaining a homogeneous mix with the same alkali solution [10,13,16]. Ratio of alkali solution to binder by weight (A/B) was also selected as an experimental variable and the values of A/B were 0.45, 0.65 and 0.85. Review of literature reveals that researchers had considered A/B ratio in the range of 0.25–0.66 for geopolymer synthesis [16–18]. However, in the present study values of A/B ratio were varied from 0.45 to 0.85 to achieve wide variation in

Table 2
Chemical and physical properties of source materials.

Source material	CaO	Al ₂ O ₃	Fe ₂ O ₃	SO ₃	MgO	SiO ₂	Specific surface area in m ² /kg
GGBS	34	20	2	0.8	8	35	800
FA	0.67	22.63	5.3	0.41	0.16	66.39	300

Na/Al ratio for geopolymer synthesis. Samples were compacted manually at a consistency of plastic limit with a tampering rod to eliminate air voids in PVC molds having diameter 38 mm and height 76 mm. Since the samples were compacted manually, it was found that at a consistency of plastic limit, desired workability for homogeneous compaction was possible. The prepared samples in molds were kept in laboratory for 24 h and then cured continuously in water for 28 days. After curing, samples were air dried at room temperature for one hour before testing. The 28 day UCS of the specimens was determined according to IS: 2720 (Part 10) [19]. Average test results of three specimens were reported as the UCS of the specimen.

2.3. Na/Al and Si/Al ratios

Previous research on geopolymer reveals that reaction kinetics of geopolymer synthesis are controlled by the atomic ratio of Na to Al (Na/Al) and Si to Al (Si/Al) in the mix and governs the strength of the product formed after geopolymerization [4,5,20,21]. Therefore, in the present study Na/Al and Si/Al for individual mixes were considered as experimental variables. Source of Na is NaOH and Na/Al ratio increases with increase in M and A/B in the mix. GGBS and FA are the source of Si and Al and Si/Al is constant for a particular binder. Again, for a particular binder, Na/Al ratio is independent of the binder percentage in the mix (but depends upon the relative proportion of the binders in a blended mix i.e. GGBS + FA). An example of calculation procedure of Na/Al and Si/Al is briefly explained in Appendix A. Calculated values of Na/Al and Si/Al of mixes with various combinations of M and A/B are presented in Tables 3 and 4. To examine the role of variation in Si/Al value on UCS, sodium silicate along with sodium hydroxide as secondary source of Si in the form of alkali activator was introduced in some mixes while maintaining a constant Na/Al ratio. Three different Na/Al ratios were chosen and for each value of Na/Al, variation in Si/Al was done accordingly as shown in Table 5.

2.4. Experimental results

28 day UCS of stabilized soil specimens with various combinations of the experimental variables are presented in Appendix B. Experimental results indicated the potential role of all the

variables in influencing the UCS but not in a same manner, both in magnitude and their resulting effect (direct or inverse).

3. Predictive model development

3.1. ANN model development

ANN has been widely used in solving various geotechnical engineering problems [22–28]. Therefore for the sake of brevity the detail discussion of ANN is refrained in the present study and can be found in literature [29–34]. An ANN based predictive model designated as ANNG (ANN model for geopolymers) was developed. ANNG has liquid limit (LL), plasticity index (PI), percentage GGBS (%S), percentage FA (%FA), molar concentration (M), alkali to binder ratio (A/B), Na/Al and Si/Al as input parameters and 28 day UCS in MPa as output parameter. ANN modeling was implemented in MATLAB R2013a environment with neural network toolbox. In order to obtain a statistically consistent training and testing data, data division of ANN model is carried out as suggested by Shahin et al. [23]. 70% of the experimental data were used for training the model and rest 30% for testing the trained model. Statistical parameters of training and testing data are given in Table 6. As a part of pre-processing, the input and output variables were normalized to fall in the range [−1, 1]. A feed-forward multilayer perceptron neural network with one hidden layer was adopted.

Number of neurons in the hidden layer was varied to find the optimum architecture. The performance of ANNG model was reported in terms of three statistical parameters namely, mean squared error (MSE), mean absolute percentage error (MAPE) and linear correlation coefficient (R). Optimum architecture of ANNG model was characterized by nine neurons in hidden layer with tan-sigmoid (hyperbolic tangent) transfer function and a pure linear transfer function at output layer. Bayesian regularization back propagation training algorithm is used for its better generalization to the training data.

3.2. MVR model development

In the present study, a multi-variable regression analysis (MVR) was also conducted to predict the UCS of geopolymer stabilized soil. Similar to ANNG model, 70% of total data were used for developing the MVR model. Rest 30% data were used to evaluate the prediction efficacy of the model. The generalized linear relationship between the dependent variable and independent variables takes the form

$$Y = a_0 + a_1X_1 + a_2X_2 + \dots + a_pX_p \pm e \quad (1)$$

where Y is dependent variable, a_0 is the Y intercept. a_1 , a_2 and a_p are the slopes associated with X_1 , X_2 and X_p . X_1 , X_2 and X_p are the values of independent variables, e is the error. “a” values are obtained via least square optimization of error. MVR model was developed with

UCS as dependent variable and LL, PI, %S, %FA, M, A/B, Na/Al and Si/Al as independent variables.

4. Results and discussion of ANN& MVR model

Statistical performance of developed ANNG & MVR model is summarized in Table 7. MSE, MAPE and R value of ANNG model for training and testing data were 3.65, 0.34 and 0.9959 & 8.34, 1.50 and 0.9823 respectively while for MVR model these values were found to be 19.20, 7.24 and 0.910 & 19.26, 8.04 and 0.899 respectively. The statistical values in Table 7 suggest that compared to MVR model, ANNG model learnt and predicted the experimental data very well. The regression plot of predicted UCS (Y) against the experimental UCS (T) of testing data of ANNG model is presented in Fig. 1. The best fitting line with $R = 0.9823$, showed a great agreement with line of equality (defined as locus of all the points where Y is equal to T). In Fig. 1 upper bound and lower bound corresponds to 99% confidence interval and refers to the likelihood of predicted values to lie in the region bounded by them over a range of experimental values. From Fig. 1, it may be observed that almost all the data points lie well within the 99% confidence interval band. Tables 8 and 9 shows the analysis of variance (ANOVA) and statistical information of predictor variables of MVR model.

Interpretation of regression analysis data in Tables 8 and 9 were made with the aid of F -test and t -test at 95% confidence level. From Table 8, it may be observed that P value ($3.43901E-68$) is very low, which suggest that with confidence level ($1-P$) almost 100%, at least one of the coefficients of MVR model is significant.

Table 7
Performance of ANNG & MVR model.

Model	Dataset	Statistical parameter		
		R	MSE	MAPE (%)
ANNG	Training data	0.996	0.34	3.65
	Testing data	0.982	1.50	8.34
MVR	Training data	0.910	7.24	19.20
	Testing data	0.899	8.04	19.26

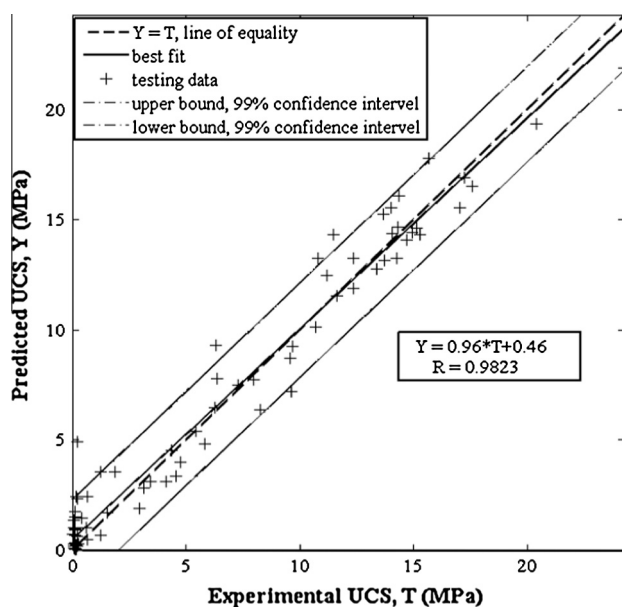

Fig. 1. Regression plot of predicted UCS against experimental UCS of ANNG model.

However, this F -test is not sufficient to identify which coefficients are significant in the MVR model. Furthermore, t -tests were conducted to identify significance of individual coefficients. Table 9 gives the t -stat and corresponding P value of individual coefficients. It is observed that P values of coefficients of LL, PI, M, A/B and Si/Al corresponds to pretty low confidence levels ($1-P < 0.95$) and are not significant for the model MVR. On the other hand P values of %S, %FA and Na/Al are fairly low with high confidence level ($1-P > 0.95$) and suggest that these coefficients are significant for MVR model. Table 9 also shows the lower and upper limit of 95% confidence interval. The fact that with 95% probability zero falls in this interval of LL, PI, M, A/B and Si/Al is consistent with the insignificance obtained from t -tests of these parameters. Confidence intervals of %S, %FA and Na/Al do not include zero and hence agrees with the significance of t -tests. Notably MVR model failed to generalize the geopolymer stabilization mechanism as it rejected the significance of LL, PI, M, A/B and Si/Al in UCS prediction.

5. Sensitivity analysis

ANN has often been labeled as “black box” because it does not provide any meaningful insight into the relative influence of input variables in the prediction process. However, methods such as Garson’s algorithm and Connection weight approach have been successfully used by some researchers for assessing variable contribution in geotechnical engineering problems [22,24,26,27]. In the present study, aforesaid two methods have been used to identify important input variables in UCS prediction. Both the methods use optimized weight vector to identify important input variables, details of which are available elsewhere [35,36]. Optimized weight vectors of the ANNG model are presented in Table 10. Based on the weights listed in Table 10 the importance and relative ranking of different input variables of ANNG using Garson’s algorithm and Connection weight approach is shown in Table 11. It may be observed from Table 11 that both the methods ranked %S as most important parameter and PI, LL as least important. Ranking given by Connection weight approach seems to be more realistic and acceptable due to following reasons:

Table 8

**Fig. 2.** Neural interpretation diagram of ANNG model.

- As the amount of binder (i.e. %S or %FA) in the mix increases, more binder is available to bind relatively lesser amount of soil, resulting in higher value of UCS. Therefore Connection weight approach ranking of %S and %FA as the most important parameters confirmed the critical effect of source material on UCS.
- Na/Al and Si/Al ratios of each specimen were independent of %S and %FA in the mix and variation of these two parameters were done by changing M, A/B and replacing NaOH with in different dosages of Na_2SiO_3 . Connection weight approach ranked Na/Al and Si/Al as most important parameters after %S and %FA. Role played by Na/Al and Si/Al in the present study is in good agreement with Duxson et al. [20] and Rees [21] for geopolymer synthesis.
- The relative importance given by Connection weight approach of %S is approximately 4.5 times of that of %FA, which is quite evident from experimental results. UCS of GGBS treated soil is much higher than that of FA stabilized soil under identical

mix proportions. GGBS is highly reactive compared to FA and dissolution extent of Si and Al element of GGBS is much higher than that of FA in geopolymer environment [5,37].

6. Neural interpretation diagram (NID)

Neural interpretation diagram (NID) is a method for visual interpretation of connection weights among the neurons [38]. Using the weights given in Table 10, a NID is presented in Fig. 2 where grey line signifies negative connection weight and black line signifies positive connection weight. Thickness of the line represents the relative magnitude of connection weight. Grey circle and black circle indicates inverse effect and direct effect respectively. It may be observed from Fig. 2 that LL and PI have inverse effect on UCS which is a justified physical representation of the stabilization mechanism.

7. Conclusions

The following general conclusions may be derived from the present study:

1. GGBS-based geopolymer stabilization is an effective method for treating clayey soil and yields much higher strength than FA-based geopolymer stabilized samples under identical mix proportions.
2. ANNG model with MLP feed-forward network and Bayesian Regularization back propagation training algorithm outperformed MVR model in predicting 28 day UCS of geopolymer stabilized clayey soil with LL, PI, %S, %FA, M, A/B, Na/Al and Si/Al as input parameters.
3. MVR model showed that %S, %FA and Na/Al are the significant parameters for UCS prediction.
4. Compared to Garson's algorithm, Connection weight approach is capable of identifying the true importance of input variables in UCS prediction.
5. According to Connection weight approach, %S is the most important parameter influencing UCS prediction followed by %FA, Na/Al, Si/Al, A/B, M, LL and PI.
6. NID demonstrated the negative or inverse effect of LL and PI on the UCS of treated soil.
7. The superiority of ANNG model over MVR model in UCS prediction can be attributed to its flexibility and adaptability in generalizing the data.

Appendix A. Example showing calculation procedure of Na/Al and Si/Al

Example

In a certain mix, let us assume that total amount of dry soil taken is x gm. Binder percentage is S, molarity is M and alkali to binder ratio is A/B

Therefore amount of binder present in the mix in gm = $(S/100) * x$

Amount of alkali solution present in the mix in gm = $(S/100) * x * (A/B)$

Again 1 molar NaOH solution contains = 40 gm NaOH in 1 l (1000 gm) water

M molar NaOH solution contains = $40 * M$ gm NaOH in 1 l (1000 gm) water.

Therefore $(1000 + 40 * M)$ gm alkali solution contains = $40 * M$ gm of NaOH

So, $(S/100) * x * (A/B)$ gm alkali solution contains = $\frac{40 * M}{(1000 + 40 * M)} * (S/100) * x * (A/B)$ gm of NaOH

Now 40 gm NaOH contains = 23 gm of Na

$\frac{40 * M}{(1000 + 40 * M)} * (S/100) * x * (A/B)$ gm NaOH contains = $\frac{23}{40} * \frac{40 * M}{(1000 + 40 * M)} * (S/100) * x * (A/B)$ gm of Na

Again, from Avogadro's No

23 gm Na contains = $6.023 * 10^{23}$ No. of Na atoms

$\frac{23}{40} * \frac{40 * M}{(1000 + 40 * M)} * (S/100) * x * (A/B)$ gm Na contains = $\frac{(\frac{S}{100}) * x * (\frac{A}{B}) * M}{(1000 + 40 * M)} * 6.023 * 10^{23}$ No. of Na atoms

Now percentage of Al_2O_3 and SiO_2 in GGBS are 20% & 35% respectively

Therefore amount of Al_2O_3 present in binder = $(S/100) * x * 0.20$ gm

Therefore amount of SiO_2 present in binder = $(S/100) * x * 0.35$ gm

Now 102 gm Al_2O_3 contains = 54 gm of Al

$(S/100) * x * 0.20$ gm Al_2O_3 contains = $\frac{54}{102} * (S/100) * x * 0.20$ gm of Al

Again 27 gm Al contains = $6.023 * 10^{23}$ No. of Al atoms

Therefore $\frac{54}{102} * (S/100) * x * 0.20$ gm of Al contains = $\frac{1}{51} * (S/100) * x * 0.20 * 6.023 * 10^{23}$ No. of Al atoms

Similarly,

It can be shown that No. of Si atoms present in the mix = $\frac{1}{60} * (S/100) * x * 0.35 * 6.023 * 10^{23}$

$$\text{Na/Al} = \frac{\frac{(\frac{S}{100}) * x * (\frac{A}{B}) * M}{(1000 + 40 * M)} * 6.023 * 10^{23}}{\frac{1}{51} * (S/100) * x * 0.20 * 6.023 * 10^{23}} \quad (1)$$

And

$$\text{Si/Al} = \frac{\frac{1}{60} * (S/100) * x * 0.35 * 6.023 * 10^{23}}{\frac{1}{51} * (S/100) * x * 0.20 * 6.023 * 10^{23}} \quad (2)$$

e.g., say $S = 20$, $\frac{A}{B} = 0.65$, $M = 14.5$, putting these values in Eqs. (1) & (2), we get

Na/Al = 1.52

Si/Al = 1.49
